All Assistant Regional Directors for Technical Services

FROM

The Director

SUBJECT

TECHNICAL BULLETIN NO. <u>///</u> SUPPLEMENTAL GUIDELINES AND PROCEDURES IN THE PREPARATION OF CHARACTERIZATION REPORTS CUM VULNERABILITY ASSESSMENT AND INTEGRATED WATERSHED MANAGEMENT PLANS USING GEOGRAPHIC INFORMATION SYSTEMS

(GIS) AND REMOTE SENSING

DATE

JUL 2 7 2015

## 1. The Technical Bulletin

This Technical Bulletin provides supplemental guidelines and procedures in the preparation of characterization reports cum vulnerability assessment and integrated watershed management plans using science-based Geographic Information System (GIS), Remote Sensing and some commonly used biophysical and socio-economic processes and methods in accordance with DENR Memorandum Circular No. 2008-05, otherwise known as "Guidelines in the Preparation of Integrated Watershed Management Plans". This will serve as guide to all regions and field implementers towards a common framework and understanding in the implementation of DMC 2008-05 as well as ensure the effective and efficient management and development of the watershed.

2. Scope and Coverage

This Technical Bulletin shall apply to all components of all watershed management and development programs and projects.

#### 3. Users of this Technical Bulletin

The intended users of this technical bulletin are personnel of DENR field offices who are involved in planning, implementing and managing of watershed programs and projects.

#### 4. Definition of Terms

- 4.1 **Watershed** refers to a land area drained by a stream or fixed body of water and its tributaries having a common outlet for surface run-off. This include small watersheds with area of 10,000 ha and below; medium scale watershed with area of more than 10,000 ha to 50,000 ha; and large scale watershed with area above 50,000 ha.
- 4.2 **Watershed Characterization** is the process of describing the biophysical and socio-economic characteristics and features of a watershed in order to have an understanding of the various processes therein.
- 4.3 **Watershed Management** is the process of guiding and organizing land and other resource uses in a watershed to provide desired goods and services without adversely affecting soil, water and other natural resources.
- 4.4 **Vulnerability** is the degree to which a system is susceptible to, or unable to cope with adverse effects of natural and manmade (anthropogenic) hazards.
- 4.5 **Vulnerability Assessment** is an analysis of the relationship between natural and anthropogenic hazards and recipient subject (watershed). The vulnerability assessment identifies the strength and weaknesses of the recipient subject in relation to the identified hazard.
- 4.6 **Geo-morphometric parameters** describe the physical feature of the watershed, in terms of ruggedness, overall shape, drainage qualities, and dissection.
- 4.7 **Watershed delineation** is the initial process in the development of management plans where the ridges and stream networks are defined to determine the extent of the landscape from which the different resources are characterized and described.
- 4.8 **Geographic Information System (GIS)** is a set of tools for collecting, storing, retrieving, transforming and displaying spatial data from the real world for a particular set of purposes (Burrough, 1986).
- 4.9 **Remote Sensing** is the technique of obtaining information about objects though the analysis of data collected by special instruments that are not in physical contact with the objects of investigation.
- 4.10 **Image classification** is defined as the process of classifying multispectral or hyper-spectral images into patterns of varying gray or assigned colors that represent clusters of statistically different sets of multiband data, some of which can be correlated with separable classes, features or materials. According to Weng

(2010), some of the basic elements of image interpretation are as follows:

- a) Tone refers to each distinguishable variation from white to black and is a record of light reflection from the land surface onto the image.
- b) Color refers to each distinguishable variation on an image produced by a multitude of combinations of hue, value and chroma.
- c) Size provides another important element in discrimination of objects and features and should be used in reference with its background.
- d) Shapes provide diagnostic information in identification such that man-made features often have straight edges while natural features tend to have irregular boundaries.
- e) Texture refers to the frequency of change and arrangement in tones.
- f) Pattern pertains to the spatial arrangements of objects.
- g) Shadow relates to the size and shape of an object.
- h) Association helps in identifying human-made features since they tend to indicate or to confirm the existence of another.
- 4.11 Vulnerability is the degree to which a system is susceptible to, or unable to cope with adverse effects of natural and manmade (anthropogenic) hazards. The Intergovernmental Panel on Climate Change (IPCC) also referred to it as the propensity or predisposition to be adversely affected.
- 5. Preparation of Characterization Report cum Vulnerability Assessment and Integrated Watershed Management Plan by the Watershed Management Planning Team (WMPT)

The multi-disciplinary and multi-sectoral Watershed Management Planning Team (WMPT) composed of representatives from the Regional Office(s), PENRO(s), sectors, LGUs, and watershed stakeholders concerned will conduct the preparation of Watershed Characterization Report cum Vulnerability Assessment and Integrated Watershed Management Plan in accordance with DMC 2008-05.

## 6. Watershed Delineation Using Hydrology and Arc Hydro Processing Tools in ARCGIS

6.1 Watershed boundary will be delineated, preferably, using the digital elevation models (DEM) derived from advanced geospatial technologies such as satellite imaging and LDAR technology.

6.2 Once the watershed boundary is determined, the geomorphometric parameters describing the physical features of the watershed (i.e., in terms of ruggedness, overall shape, drainage qualities, and dissection) will be computed using Hydrology and Arc Arc Hydro processing tools in ARCGIS, to determine the quantity and rate of water coming out of the watershed and the responsiveness of the watershed to rain events or its susceptibility to natural calamities like flood and erosion. The geo-morphometric parameters shall be computed using the following formula:

Morphometric parameter		Formula	Description	Units
A.	Linear aspects			
1.	Stream Order (µ)		Hierarchical rank	Dimensionless
2.	Stream length $(L_{\mu})$		Length of the major stream	km
3.	Total stream length $(TL_{\mu})$		Sum of all (L <sub>µ</sub> )	km
4.	$\begin{array}{cc} \text{Mean} & \text{stream} \\ \text{length}(L_{sm}) \end{array}$	$L_{\rm sm} = L_{\mu}/N_{\mu}$	$L_{\mu}$ = Total stream length of order " $\mu$ " $N_{\mu}$ = Total number of stream segments of order " $\mu$ "	km
5.	Perimeter (P)			km
	ratio(R <sub>I</sub> )	$R_I = L_{\mu}/L_{\mu-1}$	$L_{\mu}=$ Total stream length of order " $\mu$ " $L_{\mu-1}=$ Total stream length of the next higher order	Dimensionless
7.	Order length ratio (O <sub>L</sub> )	$O_L=L_\mu/L_{\mu+1}$	$L_{\mu}$ = Total stream length of order $\mu$ L $_{\mu+1}$ = Total stream length of its next higher order	Dimensionless

Morphometric parameter	Formula	Description	Units
8. Bifurcation rat	io $R_b = N_\mu/N_{\mu+1}$	$N_{\mu}$ =Total number of stream segments of order " $\mu$ " $N_{\mu+1} = Number$ of stream segments of the next higher order	Dimensionless
9.Mean bifurcation ratio	R <sub>bm</sub>	Average of bifurcation ratios of all orders	Dimensionless
10.Basin length (Lb)			km
11.Rho coefficient (ρ)	$P = R_I/R_b$	Ratio of stream length ratio and bifurcation ratio	Dimensionless
B. Relief aspects			
12.Basin relief (B <sub>h</sub> )	B <sub>h</sub> = H-h	Vertical distance between the lowest and highest points	Dimensionless
13.Relief ratio (R <sub>r</sub> )	R <sub>r</sub> = B <sub>h</sub> /L <sub>b</sub>	Ratio of basin relief and length	Dimensionless
14.Ruggedness number (R <sub>n</sub> )	$R_n = B_h x D_d$	B <sub>h</sub> =Basin relief D <sub>d</sub> =Drainage density	Dimensionless
15.Melton's Ruggedness number (MR <sub>n</sub> )	MR <sub>n</sub> =B <sub>h</sub> /A <sup>0.5</sup>	B <sub>h</sub> = Basin relief A = Area of the watershed	Dimensionless
16. Slope (S)	S= ( <u>/\</u> E/L)100%	∴E = Elev <sub>max</sub> - Elev <sub>min</sub> along the principal	%

Morphometric parameter	Formula	Description	Units
		flow path L=Length of the watershed along the main stream (by measuring the valley length and not meandering curve)	
C. Areal aspects			
17. Area (A)			Km <sup>2</sup>
18.Drainage density (D <sub>d</sub> )	Dd =TL <sub>μ</sub> /A	Ratio of total stream length	Km.km <sup>-2</sup>
19.Constant of channel maintenance	C=1/D <sub>d</sub>	Inverse of drainage density	Km.km <sup>-2</sup>
20.Circulatory ratio (R <sub>c</sub> )	$R_c=(4nA)/P^2$	watershed P=Perimeter	Dimensionless
21.Elongation ratio (R <sub>e</sub> )	$Re=(2/L_b)[(A/n)^{0.5}]$	A=Area of watershed L <sub>b</sub> =Basin length	Dimensionless
22.Compactness constant (C <sub>c</sub> )	$C_c=P/(4nA)^{0.5}$	A=Area of watershed P=Perimeter	km
23.Drainage Texture (R <sub>t</sub> )	$R_t=D_dxF_s$	The product of drainage density and stream frequency	km
24.Stream frequency	F <sub>s</sub> =N/A	Ratio between the total number of streams and area	Km <sup>-2</sup>
25.Form factor(F <sub>f</sub> )	Ff=A/L <sub>b</sub> <sup>2</sup>	A=Area of watershed L <sub>b</sub> =Basin length	Dimensionless
26.Texture ratio (T)	T=N1/P	Ratio of the	Km <sup>-1</sup>

Morphometric parameter	Formula	Description	Units
		total number of 1st order stream and perimeter	
27.Shape index (S <sub>w</sub> )	S <sub>w</sub> =L <sup>2</sup> /A	L=Length of the watershed along the main stream (by measuring the valley length and not meandering curve)	Dimensionless
28. Shape factor (S <sub>f</sub> )	S <sub>f</sub> =1/F <sub>f</sub>	Reciprocal form factor	Dimensionless
29.Length of overland flow (L <sub>q</sub> )	1/(2D <sub>d</sub> )	Od=Drainage density	km
30. Leminiscate ratio (K)	K=L <sub>b</sub> <sup>2</sup> /4A	L <sub>b</sub> =Basin length A=Area of watershed	Dimensionless

# 9

## 7. Methods and Techniques of Flora and Fauna Assessment

## 7.1 Flora Assessment

The comprehensive assessment of the vegetation data inventoried is among the crucial factors in the determination of the watershed vulnerability to environmental hazards. Stand structure and diversity analyses in this case will be computed and assessed using the following formulas:

Stand Structure	Description	
1. Density	Number per unit area	
	Density = <u>number of individuals</u> Area sampled	

Stand Structure	Description
2. Relative Density	Density relative to the abundance of other species as a function of space and/or time
	Relative Density = <u>density for a species</u> x 100 total density for all
	species
3. Frequency	Number of times the species occurs
	Frequency = number of times a particular species occurs  Total number of plots sampled
4.Relative Frequencies	Relative Frequency = <u>frequency of a particular species x 100</u> total number of species
5. Biomass	Used to express dominance of species, weight of the individuals, useful in analyzing trophic structure and flow of energy. For convenience in the analysis, foliage cover or basal area (sometimes volume) is use to express dominance
	Dominance = <u>basal area or volume for a species</u> area sampled
	Relative Dominance = <u>dominance for a species</u> x 100 total dominance for all species
6.Importance Value	Summation of relative density, relative frequency and relative dominance values for each species, standard measurement in forest ecology to determine the rank relationship of species
	Importance Value = Relative Density +Relative Frequency + Relative Dominance

## Diversity Analysis

The following parameters and formulas will be used in the biodiversity assessment analyses:

Biodiversity Parameter	Unit Value	Rationale or Importance	Formula	Data Required
Species Richness	Number of species per stratum	Ready measure of diversity	Total count of species per stratum	Number of individuals per life form
Importance Value (IV)	Relative frequency (RF <sub>i</sub> ), Relative Cover (RC <sub>i</sub> ), Relative Density (RD <sub>i</sub> )	Change in dominance structure and composition may be evaluated based on these values	IV <sub>i</sub> = RF <sub>i</sub> +RC <sub>i</sub> +RD <sub>i</sub> A limit to the number of taxa to be included here should be set accordingly (i.e., >0.5	Frequency, density and basal areas of trees in each stratum
Shannon's Index (H")	Index per stratum pooled across all plots or Index per plot pooled across strata	Indices may be used for comparison. Index is sensitive to	H'=Σ p <sub>l</sub> ln p <sub>l</sub> where pi ni/N and ni is the abundance of species I while N is the total number of individuals	Number of individuals per species
Simpson's Index (Ds)	Index per stratum poled across all plots	Indices may be used for comparison. Initially a measure of dominance but later translated to diversity	Ds= $1/\lambda$ where $\lambda$ is $\sum ni(ni-1)$ $N(N-1)$ Ni as defined above	Number of individuals per species
Evenness Measures	Index per plot	Dominance relationships may be shown by the index. Index separates the equitability component of Shannon's Index.	E=H <sub>Observed</sub> /H <sub>max</sub> , where H <sub>max</sub> is lnS and S is the number of species	Number of individuals per species
Species accumulation curves	Number of species accumulated per stratum	Plot of species accumulated relative to number of plots allows an extrapolation of the number of species.	Newly encountered species are summed and plotted against accumulated plots. Michaelis- Menten Model	Number of unique record of species per plot

Biodiversity Parameter	Unit Value	Rationale or Importance	Formula	Data Required
			was used for extrapolation	
Fisher's Index (α)	Index per stratum	This index has been shown to be useful for extrapolation especially, from data generated from small plots.	S = $\alpha ln(1+N/\alpha)$ With modification including extrapolation on $\alpha/1000$ and S/1000 basis.	Total number of species and number of individuals per stratum
Rarefaction	Number of individuals and species per stratum	The method enables the comparison of data with different sample sizes $E(S) = \sum_{n=0}^{\infty} \left\{ 1 - \left[ \left( \frac{N-N_n}{n} \right) \right] {N \choose n} \right\}$	Rarefied sample based on Hulbert's Equation. The MMF model curve fit was used to extrapolate on species per number of individuals basis.	Total number of species and individuals per stratum
Comparative studies	Species collected versus reportedly present	This method is straightforward assessment of the species collected during the field studies and those obtained from secondary data.	Listing and measuring percentage similarities	Number of collected materials
Multivariate Analysis	Plot data and pooled data for each stratum	The methods enable a visual appreciation of complex information.	Principal Component Analysis (PCA), Correspondence Analysis (CA) and Cluster Analysis (CA)	Number of individuals in plots and summarized in pooled data.
SHE Analysis	Plot data per stratum	The method allows the evaluation of species richness and equitability as unique system components. Enables the detection of abundance distribution in data.	Cummulative computation of lnS, lnE, and H as a function of abundance H' = lnS + lnE	Number of individuals in plots and summarized in successive samples

## 7.2 Fauna Assessment

The comprehensive assessment and inventory of fauna species is one of the effective tools to address emerging threats on biodiversity of a certain watershed. Knowledge on distribution, abundance, and demography of individual species are crucial input in characterization of watershed as it determines potential conservation and management strategy.

## Density Analysis

The following are methods and techniques that will be used in estimating density for wildlife species:

Method/Technique	Description/Procedure	
Total count	Direct count  Aims to count all the animals in a specific area which is called the census unit (e.g. National Park, district or any locality).	
	Should be used when:  1. the wildlife area is relatively small (under 10 km2) and oftentimes completely fenced, which means that no animals can enter or leave; and  2. a single species is being counted in a restricted area.	
Sample counts	Aims to estimate the numbers of animals in the total area within the census units from the number counted in a smaller area (sample unit).  Divide the sample units into blocks/transects then search and count the selected transects. Determine the total population estimate by multiplying the average number of animals in this sample of transects by the total number of transects across the total area (Figure 1).	
	Important assumptions:  1. that all the animals in the sample area or unit are seen and accurately counted; and  2. that animals are spread evenly throughout the whole area or census unit for which the population is being estimated.	
Index counts	A method that aims, by using a standard approach, to produce an indirect measurement of the status of the population in the total area.  An index of abundance gives an indication of the status of	
	an animal population based on the numbers of animals	

Method/Technique	Description/Procedure
	seen per unit of time or distance, in a particular area over several seasons (Figure 2).
Time-area counts     or Point counts	Count all the animals (or species) seen in an area from one point over a limited observation period (usually 30-45 min to 1 hour). Repeat the observation at several sites until index stabilizes. Estimate the density using the given formula below:
	Population Density Index (I ) = I = animals counted $\div \pi R$
Capture-mark- recapture Method	This is also known as Lincoln-Petersen method, considered as the most basic animal census procedure.  Capture, mark, and release a portion of the population. Later, capture another portion of the population and count the number of marked individuals within the sample. Determine the estimate of the total population by dividing the number of marked individuals by the proportion of marked individuals in the second sample since the number of marked individuals within the second sample should be proportional to the number of marked individuals in the whole population. Estimate the population and population range using the following formula:
	Population estimate = $N/M = (n+1)/(m+1)$
	Population range = NR = N $\pm$ (t)(SE); t95% = 1.96; t99% = 2.58
	SE = square root of $[M^2(n+1)(n-m)]/[(m+1)^2(m+2)]$
Cumulative capture-curve or Leslie graph (removal method)	Capture, mark, release (or kill) as many animal as possible, until 100% are marked (killed). Then, construct a cumulative capture curve (Leslie graph) to yield a population estimate. Apply the regression correlation below:  Y = a + bX
	Where:
	Y = no. of animals caught X = cumulative no. of animals
Standard terrestrial verte	ebrates inventory techniques/procedures:
Transect Survey of Birds	<ul> <li>✓ Establish standard line transects with routes measuring 1.5 to 2.0 kilometers. Traverse each transect route by foot at the speed of 15 minutes for every 250 meters of the transect line.</li> <li>✓ Observe transect counts of birds for a minimum of 30-40 man-hours of observation time per site.</li> <li>✓ Record the following information/ parameter in a standard data sheet: <ol> <li>species name</li> <li>number of individuals,</li> <li>perpendicular distance from the transect line (if possible),</li> <li>type of habitat</li> </ol> </li> </ul>

Method/Technique	Description/Procedure
	<ul> <li>5. elevation,</li> <li>7. strata/vertical distance from the ground and other remarks (seen or heard or flying, perched, participation in mixed feeding parties, call, foraging behavior, seen singly, in pairs or in a flock).</li> <li>✓ Employ transect counts several times a day especially during early morning, (5:30 am to 10:00 am) and late afternoon (3:00 pm to 6:30 pm), thus completing a total of 40 hours of transect counts for each site.</li> <li>✓ Determine the avifaunal composition of the study area by including each species recorded during the transect counts for the computation of Bird Species Diversity (BSD), Bird species richness (BSR), Bird species density (P), Equitability or Even Index (e = Pailey's formula, 1066)</li> </ul>
Mist-netting of Birds and Volant (flying/Gliding) Mammals (Bats)	Peilou's formula, 1966).  ✓ Mist-nets are used to catch volant vertebrates such as birds and bats. It is composed of average mesh size of 36 mm and an average height of 2.5 meters in three lengths (6.0, 12.0 and 18.0 meters).  ✓ Set-up in each site mist-netting stations composed of 15-25 nets (or 150-250 meters) and operate for 3-5 consecutive nights and days.  ✓ Keep open nets during daytime (5:00 am to 6:00 pm) to catch birds (net-day) and leave them open at night (6:00 pm to 5:00 am) to capture nocturnal birds and bats.  ✓ Set nets 2-3 meters high (as ground nets) while the bottom edges of the net at generally around a meter above the ground.  ✓ Strategically place mistnets along the tops of ridges,
	near cliffs and in patches of thick forest growth with possible flyways of understorey birds and bats.  ✓ Occasionally hoist up sky nets with a pulley and some nylon rope on top of tall tree trunks at a height of about 10-30 meters to capture upper canopy species.  ✓ Check nets for captured birds every two hours (except during rainy days where it is checked more often) from sunrise to late afternoon.  ✓ Guard nets for insectivorous bats (net-watching) from 6:00 to 8:00 p.m. and check again at 10:00 p.m., as well as 5:00 a.m. the next day.  ✓ Carefully remove netted animals from the nets and placed in cloth bags to minimize stress prior to processing
Trapping of Non- volant mammals	processing.  ✓ Bait traps with either live annelid earthworms individually tied to the traps or pieces of freshly steamed coconut meat coated with peanut butter, as well as occasional viands of fish/meat.  ✓ Set most of the traps on the ground (80-90%), often

Method/Technique	Description/Procedure
	along runways, near holes or among root tangles. Space traps at 5 to 10 meters intervals, while strategically place some of the traps on tree branches along possible pathways for arboreal species.  Take note of the position of the trap and condition of the microhabitat.  Rebait traps twice each day - during early morning and late afternoon. One trap-night is equivalent to one trap set for one night. Set an average of 300-400 trap-nights per study site.  Identify captured animals up to the species level if possible.  Take the body measurements and weight using a measuring tape/foot ruler/ dial calipers and Pesola spring scales, respectively and record them on standard field catalogues.  Take note also of the other basic information in a field catalogue sheet, i.e. sex, age, habitat, present reproductive conditions, etc.  Mark and release animals captured except for voucher specimens of probable new records whose identification needs further verification in the laboratory (i.e. examination of cranial features and its measurements).  Determine species richness, abundance, etc. by the standard number of animals captured per 100 trap-nights (trapping success).
Transect line for Herpetofauna	<ul> <li>Select and traverse a transect line similarly used for birds for each site for observations on herpetofaunal species.</li> <li>Limit observations to a maximum perpendicular distance of 25 meters on both sides of the transect. Transect lines are serviced during the day for diurnal reptiles and at night for nocturnal reptiles and amphibians.</li> <li>Note or collect species observed per transect count for verification/identification up to the species level.</li> <li>Collect either by hand, insect nets, dip nets (for tadpoles), plastic bags, sticks, pit traps, snap traps, etc. the specimens.</li> <li>Process captured individuals for body measurements (biometrics: such as snout-to-vent lengths, total length, hindlimbs length, weight etc.) and other baseline information (similarly done for birds and mammals) and record on standard field catalogue sheets.</li> <li>Later, mark and release (except for voucher specimens) them.</li> <li>Employ also the quadrant method (using small squares) in some of the sites where herpetofauna is expected. Place some ten (10) quadrants measuring 1 x 1 meter at randomly selected sites within an</li> </ul>

Method/Technique	Description/Procedure	
	area covering 100 x 100 meters. Thoroughly search these quadrants during the night especially for amphibians.	

## 8. Methods and Techniques for Socio-Economic Assessment

The following will be the methods to be used in the collection and analysis of the following variables or indicators of the socio-economic factors in the characterization of a particular watershed.

Characteristics	Purpose	Method
1) Demographic Condi	tion	
Household profile (age, sex, education, marital status, etc.)	For understanding demographic condition	Data collection and analysis
Primary and secondary occupation	-do-	Data collection and analysis
Literacy (male and female)	-do-	Data collection and analysis
Livelihood options (farm and non-farm activities)  2) Agriculture	For watershed development plans	Data collection and analysis
Cropping systems	To introduce new cropping interventions and management to bridge yield gaps	Sampling/ survey
Crop-wise input use (seeds, fertilizers, organics, pesticides, etc.)	-do-	Sampling/survey
Yields obtained	-do-	Sampling/survey
Trends in area	-do-	Historical records
Trends in cop production	-do-	Historical records
Trends in crop yield	-do-	Historical records
Land ownership	Land and water management and crop planning	Sampling/survey
Land use pattern	-do-	Sampling/ survey
Area, production and yield	-do-	Sampling/survey
Crop utilization and commercialization	-do-	Sampling/survey
Input use	-do-	Sampling/survey
Irrigation	-do-	Sampling/survey
3) Livestock		
Availability of feed and fodder	For land use and livestock planning	Data collection and analysis
Livestock breed	-do-	Sampling/survey

Characteristics	Purpose	Method
Milk production	For economic feasibility	Sampling/survey
Meat production	-do-	Sampling/survey
4) Economic Variables		
Employment (workforce and agricultural laborers)	For sources of income and availability of work	Data collection and analysis
Migration	-do-	Sampling/survey
Income across different landholdings	For land productivity and capacity	Data collection and analysis
Income and consumption	For poverty status	Data collection and analysis
Consumption expenditure	-do-	Sampling/survey
Disposable income on various activities (e.g., clothing, food, shelter, etc.)	-do-	Sampling/survey
Poverty-related indicators	-do-	Sampling/survey
Financial institutions (formal/informal)	For understanding the livelihood opportunities	Sampling/survey
5) Rural infrastructure facilities (roads, market, transport, etc.)	For watershed development plans	Sampling/survey
6) Economic feasibility of improved technologies	-do-	Sampling/survey

## 9. Image Classification and Change Detection Analysis Using ArcGIS

Whenever, satellite images are available, flora assessment by remotely sensed data will be employed through vegetation indices using ArcGIS following the steps below:

- a) Correct and calibrate available raw satellite data to remove some errors and deficiencies through image pre-processing.
- b) Apply the following pre-processing techniques methods: i) geometric correction methods; ii) radiometric correction methods; and iv) atmospheric correction methods.

i) Perform geometric correction when the images or products derived from the image are used together with other geographic data layers.

ii) Apply radiometric correction to digital image datasets to ascertain the quality and performance of the sensors. Convert digital numbers to radiance and reflectance as it is one of the most significant radiometric data activities to be done.

iii) Carry out atmospheric correction methods to remove or minimize the effects of scattering in the atmosphere before the energy reaches the earth's surface.

iv) After the pre-processing, analyze satellite images to describe the flora or vegetation indices. Evaluate the wavelengths being absorbed and reflected by the vegetation, where atmospheric water is present. Usually, flora or vegetation absorbs the red and blue wavelengths, reflects the green, strongly reflects the near infrared wavelength and displays strong absorption features in wavelengths where atmospheric water is present. Describe the flora or vegetation health, water content, environmental stress and other important related characteristics of the watershed in the assessment of such variations and relationship.

Satellite images will also be utilized to account and detect changes on flora or vegetation and climate over time. This will be carried out through the following steps:

a) Acquire thematic information through visual interpretation or computer-based digital image analysis. This will provide the descriptive data about the earth's surface such as soil, vegetation and land cover.

b) Extract metric information using principles of photogrammetry. The information that would be derived are location, height and their derivatives such as area, volume, slope and the like.

And change detection analysis across different periods will be performed using satellite images through ArcGIS to accurately account and detect change in environmental phenomena such as vegetation and climate. This will be done to understand the dynamics of change over the years and predict future trends and scenarios in the area.

#### Modelling Landslide and Flooding Vulnerability Using ArcGIS 10. Modelbuilder

A Modelbuilder will be applied to assess the vulnerability of the watershed to landslides and flooding using ArcGIS geospatial processes and techniques.

The Hydrologic Engineering Center-Hydrologic Modelling System (HEC-HMS) rainfall-runoff modelling technique will be utilized to convert precipitation excess to overland flow and channel run-off. Whereas the River Analysis System (HEC-RAS) will be employed to generate unsteady state flow through the river channel network based on the HEC-HMS derived hydrographs.

Refer to the Training Manual on Watershed Characterization and Vulnerability Assessment Using Geographic Information Systems and Remote Sensing for reference on the detailed procedure on watershed delineation using hydrology and arc hydro processing tools, image classification and change detection analysis, and modelling landslide and flooding vulnerability.
